

## 7.5 Solving Systems of Equations by Elimination

When we solve a linear system by graphing, it is not always possible to get exact values. We will look at another algebraic method that can be used to find these exact values.

### Elimination Steps:

1. Choose which variable to eliminate first ( $x$  or  $y$ ). Choose the variable that has the same coefficient in each equation. If they don't, find the lowest common multiple between the coefficients. Multiply one or both equations by a number that makes the coefficients equal.
2. Add or subtract the equations to eliminate the chosen variable.
  - a. Add equations if the chosen variable has opposite signs in each equation (one positive, one negative).
  - b. Subtraction equations if the chosen variables has the same sign in equation (both positive or both negative).
3. Solve the resulting equation in step 2 for the variable.
4. Substitute known value (found in step 3) into either original equation and solve for the other variable.
5. Check your answer using both equations.

Examples: Solve by Elimination

①  $2x + y = -7$

a) ②  $x + y = -4$

every term in equation ② is subtracted

$$\begin{array}{r} \textcircled{1} \quad 2x + y = -7 \\ - \textcircled{2} \quad x + y = -4 \\ \hline x + 0 = -3 \end{array}$$

$x = -3$

Now solve for "y"

$$\begin{array}{r} \textcircled{2} \quad x + y = -4 \\ -3 + y = -4 \end{array}$$

the "y" coefficients are the same so we'll subtract equations.

①  $3x + 2y = 9$   
②  $-3x - 5y = -15$

the "x" coefficients are equal and opposite signs so we'll add equations

$$\begin{array}{r} \textcircled{1} \quad 3x + 2y = 9 \\ \textcircled{2} + (-3x - 5y = -15) \\ \hline 0 - 3y = -6 \\ -3y = -6 \\ \frac{-3y}{-3} = \frac{-6}{-3} \end{array}$$

$y = 2$

verify :

$$\begin{array}{r} \textcircled{1} \quad 2(-3) + (-1) \stackrel{?}{=} -7 \\ -6 - 1 = -7 \quad \checkmark \end{array}$$

$$\begin{array}{r} \textcircled{2} \quad -3 + (-1) \stackrel{?}{=} -4 \\ -3 - 1 = -4 \quad \checkmark \end{array}$$

$$\begin{array}{r} \textcircled{1} \quad 3x + 2y = 9 \\ 3x + 2(2) = 9 \\ 3x + 4 = 9 \\ \quad -4 \quad -4 \\ \frac{3x}{3} = \frac{5}{3} \end{array}$$

$x = \frac{5}{3}$

$$\begin{aligned} \textcircled{1} & 2x - 3y = 15 \\ \textcircled{2} & 5x - 2y = 10 \end{aligned}$$

$$\begin{aligned} \frac{2}{3}x - \frac{1}{2}y &= 4 \\ \text{d) } \frac{1}{2}x + \frac{1}{4}y &= \frac{5}{2} \end{aligned}$$

Neither variable has matching coefficients.

Choose to eliminate "x" first.  
Find lowest common multiple between 2 and 5 (it's 10).

Multiply equation  $\textcircled{1}$  by 5  
Multiply equation  $\textcircled{2}$  by 2

$$\textcircled{1} \quad 5(2x - 3y = 15) = 10x - 15y = 75$$

$$\textcircled{2} \quad 2(5x - 2y = 10) = 10x - 4y = 20$$

$$\textcircled{1} \quad 10x - 15y = 75$$

$$\textcircled{2} \quad - (10x - 4y = 20)$$

$$0 - 11y = 55$$

$$\frac{-11y}{-11} = \frac{55}{-11}$$

$$y = -5$$

$$\textcircled{1} \quad 2x - 3y = 15$$

$$2x - 3(-5) = 15$$

$$2x + 15 = 15$$

$$-15 \quad -15$$

$$\frac{2x}{2} = \frac{0}{2}$$

$$x = 0$$
